the first kind of tree we encountered
was an **expression tree**

we now have a way to
represent **trees** in python

we now have a way to represent **trees** in python

```
def tree_node(l, lbl, r):  
    return [l, lbl, r]  
  
def leaf(lbl):  
    return tree_node(None, lbl, None)  
  
def example_expression_tree():  
    eight = leaf(8)  
    five = leaf(5)  
    negative_two = leaf(-2)  
    two = leaf(2)  
    max_node = tree_node(negative_two, max, two)  
    min_node = tree_node(eight, min, five)  
    root = tree_node(min_node, pow, max_node)  
    return root
```

can we also write code to
evaluate an expression tree?

recall that we evaluate
an expression tree
"bottom-up"

so leaf nodes are easy to evaluate

```
def evaluate(etree):  
    if is_leaf(etree):  
        return label(etree)
```

the value of a leaf
node is just its label

the value of a **non-leaf** is its label (a function)
applied to the values of its children

```
def evaluate(etree):  
    if is_leaf(etree):  
        return label(etree)  
    else:  
        func = label(etree)  
        left_value = evaluate(left(etree))  
        right_value = evaluate(right(etree))  
        return func(left_value, right_value)
```

this is an example of a
recursive function

```
def evaluate(etree):  
    if is_leaf(etree):  
        return label(etree)  
    else:  
        func = label(etree)  
        left_value = evaluate(left(etree))  
        right_value = evaluate(right(etree))  
        return func(left_value, right_value)
```

a **recursive** function
is a function that **calls itself**

```
def evaluate(etree):  
    if is_leaf(etree):  
        return label(etree)  
    else:  
        func = label(etree)  
        left_value = evaluate(left(etree))  
        right_value = evaluate(right(etree))  
        return func(left_value, right_value)
```

The diagram illustrates the recursive nature of the `evaluate` function. A pink arrow originates from the `evaluate` function call in the line `left_value = evaluate(left(etree))` and points back to the `def evaluate(etree):` line. Another pink arrow originates from the `evaluate` function call in the line `right_value = evaluate(right(etree))` and also points back to the `def evaluate(etree):` line. These arrows visually demonstrate how the function calls itself during its execution.

recursion is appropriate when we can solve a **task** by breaking it into **smaller versions** of the same task

we can compute the value of **this** tree

if we can compute the values of **these** trees

by breaking up the task into smaller and smaller tasks, eventually the tasks become small enough to solve directly

these "small enough"
tasks are called
base cases

```
def evaluate(etree):  
    if is_leaf(etree):  
        return label(etree)  
    else:  
        func = label(etree)  
        left_value = evaluate(left(etree))  
        right_value = evaluate(right(etree))  
        return func(left_value, right_value)
```
